Overview

GaN-based solar cells with InGaN multiple quantum wells (MQWs) are promising devices for application in space environment, concentrator solar systems, wireless power transmission and multi-junction solar cells.

GaN-based solar cells with InGaN multiple quantum wells (MQWs) are promising devices for application in space environment, concentrator solar systems, wireless power transmission and multi-junction solar cells.

What is needed for cost-effective, high efficiency solar cells?

Spectral insensitivity?

Can we get the same material quality as GaAs, but with a lower bandgap alloy?

How to extend the absorption edge?

How to extend the absorption edge?

How to extend the absorption edge?

How to extend the absorption.

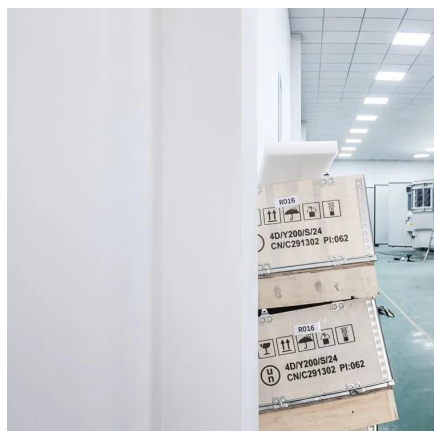

This work shows the design of a high-efficiency solar cell in an indium-gallium-arsenide/-gallium-arsenide multiple quantum well (MQW) structure. The main concerns regarding the solar cell are its fabrication complexity, design complexity, and efficiency. Tandem solar cells are designed to absorb.

InGaN/GaN multiple quantum well (MQWs) solar cells are promising devices for application in harsh environments. However, understanding their degradation kinetics can be complicated by the high periodicity of the active region (AR). To overcome this issue, we carried out an experiment on structures.

A changeable band gap and radiation hard ternary indium gallium nitride (InGaN) with multiple quantum well (MQW) structure-based solar cell is numerically modelled and analysed for a better power source in space mission using modern TCAD tool. Since InGaN has direct band gap varying from 0.7 to 3.4.
